1. Write a program that takes two strings from the user: first name, last name. Pass these variables to full name function that should return the (full name). o For example: ▪ First name = "your first name", last_name = "your last name" ▪ Full_name = "your full name"

1a) Write function named "string_alternative" that returns every other char in the full_name string. Str = "Good evening" Output: Go vnn

```

1  import os
2
3  def count_words(line):
4      words = line.split()
5      word_count = {}
6      for word in words:
7          word_count[word] = word_count.get(word, 0) + 1
8      return word_count
9
10 # Get the current working directory
11 current_directory = os.getcwd()
12
13 # Set the input file path relative to the current directory
14 input_file_path = os.path.join(current_directory, 'input.txt')
15
16 with open(input_file_path, 'r') as file:
17     content = file.read()
18     Ae = [line.strip() for line in content.split('\n')]
19
20 # Concatenate stripped elements into a single string
21 concatenated_string = " ".join(element.strip() for element in Ae)
22
23 # Strip again and get word count
24 word_count = count_words(concatenated_string)
25
26 # Set the output file path relative to the current directory
27 output_file_path = os.path.join(current_directory, 'output.txt')
28
29 # Write the content and word count to an output file
30 with open(output_file_path, 'w') as output_file:
31     output_file.write("Input Content:\n")
32     output_file.write(content + '\n\nWord_Count:\n')
33     for word, count in word_count.items():
34         output_file.write(f'{word}: {count}\n')
35
36 # Print the content of the input file
37 print("Content in file:")
38 print(content)
39
40 # Print the word count
41 print("\nWord_Count:")
42 for word, count in word_count.items():
43     print(f'{word}: {count}')
44
45 print(f"\nOutput written to {output_file_path}")

3. Write a program, which reads heights (inches.) of customers into a list and convert these heights to centimeters in a separate list using: 1) Nested Interactive loop. 2) List comprehensions Example: L1: [150,155, 145, 148] Output: [68.03, 70.3, 65.77, 67.13]

```
height.py > ...
1 inches = []
2 print ("Enter heights in inches. Type 'done' when finished.")
3 while True:
4     x = input("Enter height in inches(or 'done' to finish): ")
5     if x.lower() == 'done':
6         break
7     try:
8         height_inch = float(x)
9         inches.append(height_inch)
10    except ValueError:
11        print("Invalid input. Please enter a valid number or 'done'.")
12 centimeters = [height * 2.54 for height in inches]
13 print("Heights in Inches:", inches)
14 print("Heights in centimeters:", centimeters)
